# 16.89 / ESD 352 Final Design Review 

May 15, 2006

## The 16.89 / ESD 352 Team

Presenting today:<br>Scott McCloskey<br>Seungbum Hong<br>Allan Fong<br>(Systems Team 3)

## Presentation Overview

- Design Challenge
- Executive Summary
- Mobility System Architecture Analysis
- Mobility System Design
- Approach
- Assumptions
- Subsystems
- Vehicle Selection
- Commonality
- Integrated Dynamic Capability Analysis (MUSE)
- Communication and Navigation
- Conclusions and Future Work

### 16.89 / ESD 352 Design Challenge

- This year's 16.89/ESD. 352 Space Systems Engineering class will engage in the question of how to best architect and design a future, extensible planetary surface transportation system. The system will be designed for the Moon with considerations for eventual adaptation to Mars. In addition, the class will consider how a terrestrial version of the lunar transportation system can be built for testing in lunar and Mars analog sites on the Earth.

## DRMs and Architecture Selection

- Broke down activities into 4 Design Reference Missions (DRM):
- DRM-1
- Explore up to 20 km radius on one EVA
- 60 km range total
- DRM-2
- Explore up to 100 (Moon) - 200 km (Mars, Earth) radius over a duration of 5 - 10 days
- 300-600 km range total
- DRM-3
- Resupply the base with cargo located up to 2 km away
- DRM-4
- Use mobility assets to build and maintain the infrastructure of the outpost
- Architecture analysis:
- 2 2-person UPVs for short range exploration
- 3 2-person UPVs and 2 campers for long range exploration

## Vehicle Analysis Summary

- Done iteratively in MATLAB
- Lunar exploration:
- 3810 kg camper
- 374 kg UPV
- Commonality
- Camper: Fix chassis geometry
- UPV: Design chassis for Moon and Mars
- Dynamic capability analysis done with MUSE

16.89 / ESD 352 Space Systems Engineering

Slide 5/94

## Earth, Moon, Mars Transportation

- Earth
- Use of regular ATVs such as those currently present at Mars Haughton (delivered by Twin Otter plane)
- Minimalist solution, possible because no towing required
- Transportation of camper
- Delivery to Resolute Bay using barge, drive to Haughton-Mars over the ice (like Humvee at Haughton-Mars)
- Likely the most cost-effective solution, although time consuming
- Notional schedule: ship during the summer, drive over the ice the following winter
- Moon
- Delivery of UPVs and campers with a dedicated cargo launch (1 CaLV, 15-20 mt delivery capacity)
- Alternatively: delivery of campers as re-supply vehicles for a lunar outpost, delivery of UPVs with crew, no dedicated CaLV launch required
- Mars
- Delivery of UPVs and campers with a dedicated launch of a CaLV

## Mobility System Architecture Analysis

16.89 / ESD 352 Space Systems Engineering

## Key Ground Rules \& Assumptions

- Earth, Moon, and Mars systems are used for both exploration and operational testing / improvement
- The mobility architecture selection is driven by DRM-1 and DRM2 operations on the Moon and Mars
- Earth system employs Moon / Mars architecture for operational commonality
- Mobility system masses and geometries have to be within transportation system capabilities for Earth, Moon, and Mars
- Earth appears to be most stringent if existing capabilities are used
- Crew operates always in groups of at least two
- Worst-case overhead over straight-line distance is 1.5 (3 for round-trip)
- Derived from Apollo traverses; factor 1.5 for intentional deviations from straight-line (e.g. Apollo 17 EVA-3)

## Surface Mobility Element Model

- Three different types of vehicles can be modeled I sized parametrically on subsystem level:
- Open rover
- Can tow other elements
- Can hold cargo
- Provides accommodations for crew in EVA suits

- Camper
- Provides pressurized environment for crew
- Is not capable of driving without towing vehicle

- Pressurized rover
- Provides pressurized environment for crew
- Is self-propelled
- Can be utilized to tow other elements

Image credit: from Draper/MIT CE\&R report, 2005

## Model Flow

- Model provided by Afreen and Seungbum
- Metrics
- Mobility system mass
- Minimize this metric
- Output from vehicle model
- Number of science sites visited
- Maximize this metric
- Calculated using inputs to vehicle model
- Risk, extensibility, performance with loss of asset, and vehicle size were treated as constraints on the architectures

## Common ("Fractal") Operations Approach

- DRM-1 excursions represent local traverses in the vicinity of a pressurized habitat, not unlike traverses on Apollo J-type missions
- DRM-2 excursions represent long-range excursions 10s to 100s of km away from the outpost and require independent habitation
- Organizing the DRM-2 excursions into traverse days and exploration days provides the opportunity for conducting DRM-1 excursions from the mobile habitat much like from the outpost
- Potential cost / risk reduction and learning effects from operational commonality, reuse of procedures

## DRM-1 Architecture Options

vehicles

- DRM-1 traverses ( 60 km range) can be carried out with the entire crew, or leaving behind part of the crew back at base $/$ at the LSAM
- Apart from exploration, DRM-1 traverses are also relevant for accessing the base in case of a long landing (in this case all crew have to be transported)
- All crew on traverse have to be able to return to base in case of an SPE and after loss of one unpressurized vehicle within 3 hours
- For each option, average speed was varied from $10-20 \mathrm{~km} / \mathrm{h}$, and different power generation technologies were analyzed

## DRM-2 Architecture Options

| Pressurized |
| :---: |
| vehicle type |

\# of crew on
traverse
\# of pressurized
vehicles

Unpressurized mobility configuration

- Pressurized and unpressurized vehicles drive at $15 \mathrm{~km} / \mathrm{h}$ average speed
- Unpressurized vehicles are sized such that they can carry excess crew in case of loss of one unpressurized vehicle during DRM-1 type operations
- All vehicles utilize fuel cells (independent of sunshine and solar elevation, more efficient than batteries)
- Pressurized vehicles provide protection and life-support to wait out a SPE

## Example Trade Space (Lunar DRM-2)

## Architecture Sensitivity Analysis

- Examined sensitivity to model inputs:
- DRM-1
- Range (30-70 km)
- Speed (8-18 km/hr)
- DRM-2
- Sortie Days (3-10 days)
- Range (240-360 km for Moon, 480-720 km for Mars)
- Speed (8-16 km/hr for Moon, 6-16 km/hr for Mars)
- Variation of these parameters had no major impact on the final architecture selection

## Lunar Architecture Selection

- 2 2-person campers and 3 unpressurized rovers sized for towing a camper
- 2 of the same unpressurized rovers are used for mobility on sortie missions
- Rationale:
- 1 pressurized vehicle is not acceptable because long-range exploration capability is lost when this vehicle is damaged / permanently unavailable
- 2 pressurized vehicles provide more safety margin
- Assumed that the lunar base can be left unattended for short
 periods of time.

## Mars Architecture Selection

- 2 2-person campers and 4 unpressurized rovers sized for towing a camper
- Rationale:
- 1 pressurized vehicle is not acceptable because long-range exploration capability is lost when this vehicle is damaged I permanently unavailable
- 2 pressurized vehicles provide more safety margin
- It is assumed that the base is never unattended on Mars (2 crew stay behind)
- 1 additional unpressurized vehicle is left behind at the base during
 long-range exploration

## Camper vs. Pressurized Rover

- Utilizing a pressurized rover in concert with unpressurized vehicles (UPVs) results in duplication of functionality:
- Additional functionality for steering and navigation in pressurized rover (cockpit)
- This additional functionality results in a power, volume, and mass penalty compared to using a camper (excess mass must be transported during the entire traverse)
- Using campers that are guided by UPVs represents a minimalist solution to long-range surface mobility
- Camper crew compartment is inherently similar to the human lunar lander crew compartment (option for commonality, synergy)

## Mobility System Design

16.89 / ESD 352 Space Systems Engineering

## Mobility Design Approach

- First design the lunar camper and UPV for DRM 1 \& 2, then study the delta to Earth and Mars designs
- Vehicle design is broken down by subsystem and coded into MATLAB modules
- Vehicle characteristics are determined by iteratively running each subsystem module
- MUSE verifies the feasibility of vehicles' design

## Basic Assumptions

- 2 crews for camper, 2 crew for UPV
- Total excursion days: 7 days
- Number of driving day: 4 days
- Number of consecutive driving days: 2 days (?)
- Driving or working time per day: 12 hr/day
- Number of EVAs per excursion: 7
- Number of traverses over the lifetime of the vehicle: 125
- ECLS regeneration on camper
- Number of wheels: 4
- Driving system on Camper \& no steering system on Camper
- UPV guides Camper, not tows
- Al structure and chassis

## Interface

## Comparison of TVM \& PSV

| TVM | PSV |
| :--- | :--- |
| Power storage on camper | Power storage on UPV |
| Driving motor on camper | No driving motor on camper |
| UPV GUIDEs a camper | UPV TOWs a camper |
| Radiation protect system | No radiation protect system |
| Consideration of terrain roughness | No consideration of terrain roughness |
| More detail model on thermal, comm | Simple model on thermal, comm |
| Consideration of living space | No consideration of living space |

16.89 / ESD 352 Space Systems Engineering

## Human Activities Module (1)

- Assumptions
- No Kitchen - MRE's (American)
- No Bunks - Astronauts kip on hammocks spanning width of living space
- Living space is rectangular
- Ceiling is the curved interior wall of "can"
- All space outside living space is usable for storage/supplies
- Basis
- HSMAD
- PSV Model
- Personal Experience RV'ing across USA while growing up

## Human Activities Module (2)

- Function
- Volume
- Living space volume determined by summing volumes of things needed per person per excursion that exist in living space
- Storage space volume determined by summing volumes of things needed per person per excursion that may be stored
- Mass
- HA mass determined by summing volumes of things needed per person per excursion
- Power
- Power determined by summing items that draw power for living, EVA's, and interior work

## ECLS System Model (1)

Assumptions, ground rules:
-ECLS is only required on the camper -The camper is continuously operated for excursions of 1-2 weeks duration -Over the lifetime of the camper, on the order of 100 such excursions can occur

ECLS functionality:

Mathematical model is based on equipment parameters provided by HSMAD [1]

| Provide O2 \& N2 storage |
| :--- |
| Provide O2 \& N2 feed and control |
| Provide trace contaminant control |
| Provide CO2 filtering |
| Provide CO2 drain and storage |
| Provide CO2 rejection |
| Provide food to crew |
| Provide water storage |
| Provide water filtration and regeneration |

## Major ECLS system interfaces:

- To human factors / accommodations: waste management
- To power generation + storage (required power)
- To thermal control (waste heat)
- To structure (mounting, structural integrity)
- To astronauts, cabin atmosphere
- To avionics (control, crew interfaces)

## ECLS System Model (2)

Baseline ECLS system design:

ECLS functionality for different use cases / planetary surfaces:

| Planetary surface | Earth | Moon | Mars |
| :--- | :---: | :---: | :---: |
| Provide O2 \& N2 storage |  | x | x |
| Provide O2 \& N2 feed and control |  | x | x |
| Provide trace contaminant control |  | x | x |
| Provide CO2 filtering |  | x | x |
| Provide CO2 drain and storage |  |  | x |
| Provide CO2 rejection |  | x | x |
| Provide food to crew | x | x | x |
| Provide water storage | x | x | x |
| Provide water filtration and regeneration | x | x | x |

## Example legacy hardware:

Shuttle condensing
heat exchanger
ISS cabin fan

ISS water multi-filtration device (hardware)

- ECLS system extensibility:
- Mars use case requires most functionality due to difficulty in CO2 rejection
- Food and water management are common for all three use cases
- Platform should be lunar design with scarring for Mars CO2 drain, storage and rejection
- Design should be modular so that atmosphere management components can be removed for Earth use case

## Thermal Module (1)

- Environmental Inputs
- Solar energy from sun
- Albedo effects
- IR emission from surface
- Vehicle Inputs
- Driving heat produced
- Sci. time heat produced
- Surface area of vehicle
- Average environment heat flux
- Vehicle type
- Sizing
- Heat flow problem: need more heat dissipation or retention?
- Based on HSMAD parametric values
- Trade
- Vertical radiator
- Bi-directional heat radiation
- Additional structural mass
- Horizontal radiator
- Less structural mass
- Uni-directional heat radiation
- Outputs
- Total thermal volume
- Thermal mass on chassis
- Thermal pressurized mass
- Thermal driving power
- Thermal science time power
- Verification
- LRV (for upv only)

## Thermal Module (2)

- Assumptions
- Paint absorptivity: 0.2
- Paint emissivity: 0.8
- 1.2 factor on heat inputs
- Radiators on top of camper for better heat dissipation
- Heat dissipation
- Radiation only on Moon
- Radiation, convection on Mars
- Convection on Earth
- Size radiator and support structures to dissipate higher value of heat
- "Delta" between environments can be found, but no redesign of internal fluid paths
- Components

| MLI | fluids |
| :--- | :--- |
| Heat pumps | plumbing |
| radiators | louvers |
| controls | Structural <br> support |

## Radiation Module (1)

- Environmental Inputs
- Average GCR
- Solar Particle Events
- Vehicle Inputs
- Surface area of airlock
- Vehicle type
- Sizing
- Keep under NASA radiation requirements
- 50 REM per year
- Trade

| Water | Aluminum |
| :--- | :--- |
| Lithium Hydride | Polyethylene |
| Liquid hydrogen | Liquid methane |

## Radiation Module (2)

- Assumptions
- Use additional shielding provided by airlock structure, vehicle structure, other components to stop radiation
- SPE protection sized based on the 6 solar particle events in 1989
- Worst case scenario with GCR at solar minimum plus these events
- Astronauts sleep in airlock, which is also the safety vault, so no need to place shielding elsewhere
- Large reduction in mass
- Major questions to answer
- How much radiation is stopped by Mars atmosphere?
- How much lead time will astronauts have before an SPE hits?
- Technology improvement (SOHO, etc)
- Long-term effects of GCR on cancer risks?
- Verification of materials for effectively stopping GCR
- Polyethylene proved ineffective on ISS at stopping GCR cascading effects

## Structures (Crew Compartment)

- Assumptions for the model
- Shell thickness will be sized based on pressure difference
- Does not assume different dynamic failure modes
- Inputs
- Human activity dimensions (width and length)
- Internal crew stations dimensions
- Environment conditions
- Outputs
- Structure mass
- Structure volume
- Surface area for radiation system
- Surface area for thermal system

## Structures (Crew Compartment) (2)

- Interfaces
- Human activities
- Thermal
- Radiation
- Chassis
- Description
. Skeleton frame material is AI-2219
- Shell material is AI-7075
- Internal pressure kept at 10.2 psi or 0.694 atm
- Frame includes 6 horizontal supports and 4 cross-section ribs
- Reference
- Framework and thickness of skeleton based on airplane specifications
- Earth, Moon, Mars Extensibility?
- Major factors that will change
- External pressure: size the thickness of the shell
- Gravity: loading forces

## Chassis

- Assumptions for the model
- Ladder chassis
- Uniform vertically distributed load
- Calculated for an allowable maximum deflection of 0.02 m
- Inputs
- Structure dimensions (length and radius)
- Wheel diameter
- Total mass needed to be carried by the chassis
- Environment conditions
- Outputs
- Chassis dimensions (wheelbase, track, height)
- Chassis mass
- Free chassis volume

## Chassis (2)

- Interfaces
- Human activities
- Payload
- Structures
- Propulsion
- Various other subsystem volume and masses
- Description
- Beams have square solid cross-sections
- 2 side rails and 3 cross bars
- Free chassis volume calculated includes volume between the chassis and the crew compartment
- Reference
- Based off ladder model and PSV assumptions
- Earth, Moon, Mars Extensibility?
- Major factors that will change
- Gravity: loading forces

## Propulsion: A Few Changes

## Propulsion: Inputs and Outputs

## Terrain Characterization

Sample terrains for simulation generated from relationships in Apollo and post-Apollo geological literature

Table 2. physical and mechanical properties of lunar soll simulants

## Traverse Performance

$$
h \leq 0.5\left(\left(D_{W}+D_{O}\right)-\sqrt{\left(D_{W}+D_{O}\right)^{2}-b^{2}}\right)
$$

Based on geometric navigability of obstacle field, combined with path planning constrained by vehicle geometry and dynamics

## Steering

- Assumption
- Electronic power steering
- Wheel turning angle is $5 \mathbf{0}^{\boldsymbol{\circ}}$
- Inputs
- \# of steered wheels
- Sprung mass
- Wheel base, track
- Outputs
- Steering mass
- Turning Radius

## Steering (2)

- Interfaces
- Chassis
- Various other subsystem masses
- Description
- Ackerman steering model
- Reference
- Motor Truck Engineering Handbook, pg 326

## Power Module

- Inputs
- Power levels for various power modes from each subsystem
- Traverse duration
- Energy needed for UPV science traverse
- Outputs
- Power subsystem mass and distribution
- Thermal power to dissipate
- Amount of water produced

## Power Module (2)

- Power is stored in primary fuel cells
- From the power usage and times, calculates energy and sizes the fuel cell reactants
- From the peak power, sizes the distribution and conversion components
- Based largely on the PSV code and adapted for our TVM
- Extensible to Earth and Mars

## Suspension

- Assumption
- Quarter-Car Model
- Passive Control
- Inputs
- Sprung mass
- Wheel mass
- Tire Stiffness

- Outputs
- Spring Stiffness
- Damping Coefficient
- Suspension Mass

## Suspension (2)

- Interfaces
- Propulsion
- Various other subsystem masses
- Description
- $a_{\text {RMS }}=\sqrt{\frac{1}{T} \int_{0}^{T} a_{w}^{2}(t) d t}$
- Evaluate the vibration of the vehicle against ISO 2631-2 criteria
- Reference

- Theory of Ground Vehicles, Wong, 1978
- ISO 2631-2

## Camper Design Specifications

## UPV -Camper Combination

16.89 / ESD 352 Space Systems Engineering

## Vehicle Analysis

## Commonality, Sensitivity, and Extensibility for Different Environments

16.89 / ESD 352 Space Systems Engineering

## Vehicle Sensitivity Analysis

- Used PSV model to determine effects planet has on the design
- Analyze mass of subsystems on different planets, multipliers, and absolute differences
- Important scaling factors

| System | Earth | Mars |
| :--- | :--- | :--- |
| Chassis | gravity $\left(9.8 \mathrm{~m} / \mathrm{s}^{\wedge} 2\right)$ | gravity $\left(3.3 \mathrm{~m} / \mathrm{s}^{\wedge} 2\right)$ |
| ECLSS | breathing-air ventilation | CO2 control |
| Human activities | no airlock | similar to Moon |
| Propulsion | terrain and gravity | terrain and gravity |
| Radiation | None required | thickness, environment |
| Shell structure | external pressure | external pressure |
| Power | Temperature difference | Temperature difference |
| Thermal | Heat absorb, convection | Heat absorb |

## PSV Camper Sensitivity to Surface Environment

- Mass variation from the Moon design:
- Earth: crew station, chassis, propulsion
- Mars: chassis, propulsion, power
- Subsystems are predominately most massive in Mars design

| PSV Camper | Mass (kg) |  |  | Ratio |  | Absolute Difference |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Moon | Earth | Mars | Mars/Moon | Earth/Moon | Moon-Earth | MoonMars |

## Commonalities

- Highlights major varying subsystems
- 2 design options

## Vehicle Commonality Conclusion

- Fix chassis geometry
- Common chassis design for different environments
- Vary beam profiles to account for different loads
- Allows for swappable subsystem modules
- Reduce multiple chassis design cost
- Crew station, wheels and propulsion need to be modified based on terrain and external environments
- UPV design for Moon and Mars
- Customize existing ATVs for Earth operations
- Over-designed UPV chassis can be beneficial to DRM 3 and DRM 4 operations on the moon

## DRM 3 and DRM 4 Briefly Revisited

- DRM 3
- Resupply within 3km
- Move cargo from lander to base (lifting, towing)
- Astronaut manipulable "briefcases" (~100 kg)
- Medium-size modules that need manipulation assistance (~500 kg)
- Large pallets with built-in mobility ( $\sim 2 \mathrm{mt}$ )
- Moon outpost mission: 7.3 mt for consumables
- DRM 4
- Infrastructure buildup within 3km
- Move regolith to provide blast protection, radiation/thermal shielding, initial ISCP
- Deploy small equipments
- Connect base modules with wires, etc.
- Light surface construction
- Cable bundle estimate: 300 kg and 0.3 m3
- Large science instruments are ~25 kg
- Estimated mass: 250-300 kg for backhoe, $150-200 \mathrm{~kg}$ for dozer blade

## Extensibility DRM 3 and DRM 4

- Approximate horizontal force ~ 6x10^6 N
- Approximate digging/lifting force ~2,296 N
- Plowing ~6x10^6 N
- Lifting capacity $\sim 1,408 \mathrm{~kg}$
- Bucket Capacity ~ 0.04 m^3
- Average regolith density ~ $1,250 \mathrm{~kg} / \mathrm{m}^{\wedge} 3$
- Moon gravity ~ 1.63 m/s^2

## Integrated Dynamic Capability Analysis (MUSE)

16.89 / ESD 352 Space Systems Engineering

## Mission Utility Simulation Environment (MUSE)

16.89 / ESD 352 Space Systems Engineering

## Roles of MUSE

- Validation tool of vehicle capabilities
- Vehicle architecture design ("static" model)
- MUSE ("dynamic" model)
- Iterative design
- Enables debugging of vehicle model and MUSE simulation
- Enables convergence to overall design
- Identification of consumable modularity opportunities
- Environment incorporating all the key components:
- Terrain
- Vehicle design
- Logistics (consumables, human activities)

## DRM-1 \& DRM-2 Exploration Strategies

- Four DRM-1 exploration types

## Spiral

Search in expanding circle around origin

Loop
Travel out and come back on different path

Area Search
Travel to distant site and explore sites in vicinity

## Grid Search

Travel to sites along survey grid lines

- Each location is either a "site" or a "region" (collection of four closely-spaced sites)
- Locations of interest are $\sim 3 \mathrm{~km}$ apart (from Apollo)
- DRM-2: drive directly to camp site, perform DRM-1's

## DRM-1 Simulation Tsiolkovsky Crater

MUSE DRM-1 Simulation

Number of sites visited: 0

# Modeling DRM-1 <br> Traverse 

Site

Propagate over Terrain Decrement energy Increment time

Spend time at site/region Increment payload Increment time

Check constraints: If don't have enough time/energy to get to next site, drive back

## Modeling DRM-2

## Modeling Propulsion-Terrain Interaction

## Constraints

- MUSE guarantees vehicles always return to base
- Enforce time and energy capacity constraints

## Statistics of Excursions in MUSE

- Run the DRMs with multiple different parameters
- Can get statistical sampling of excursions
- Try to abstract out site selection / terrain as much as possible
- Changed the following parameters
- Exploration Types (search patterns)
- Science site types (site vs. region)
- Operations at science sites
- Origin locations (DRM-1)
- Hab \& Camp Locations (DRM-2)

## Design Iterations: Vehicle Model $\leftrightarrow$ MUSE

- Results of first iteration
- UPV energy storage was far too high
- Used only 10-25\% of energy stored onboard
- Camper had insufficient power to reach camp (no exploration possible)
- Feedback to vehicle design team
- Reviewed power consumption strategies
- Verified propulsion model
- Modified design selections
- Removal of some power consuming items
- Lowered energy capacity on UPV

CDF of remaining energy capacity onboard at end of DRM-1 excursion

Min remaining: 76\%
Max remaining: 95\%

- $2^{\text {nd }}$ iteration design input into MUSE for final results

## Results: Energy on DRM-1

## At the end of a DRM-1 excursion...

$6 \%$ chance of using some of the $15 \%$ safety margin

## Results: Sample Collection on DRM-1

## At the end of a DRM-1 excursion...

$30 \%$ probability of running out of sample mass capacity

CDF of Sample Volume Capacity Remaining on UPV upon Return to Base for DRM1

Always have at least $77 \%$ sample volume capacity available

## Results: Exploration Capability on DRM-2

Once at the camp during DRM-2...

- Evaluate remaining resources after the camper travels from hab to camp
- Find the number of DRM-1 excursions that are possible at the campsite using resources on camper
- Assume all consumables for DRM-2 are on camper
- No additional supplies brought specifically for exploration

## Results: Exploration Capability on DRM-2

Energy Diagram for DRM2 Mission 2

Energy Diagram for DRM2 Mission 1

## DRM-1 Capability Metric Results

- Metric: number of sites per excursion
- Expectation: 5.71
- Standard Dev: 3.02

## DRM-2 Capability Metric Results

Histogram of Energy Available for DRM-1 Activies

- Metric: number of
DRM-1s per DRM-2
- Expectation: 0.80
- Standard Dev: 0.75
- Next camper design iteration should have more energy onboard
\# of DRM-1s

## Consumable Modularity Comments

- Modularity of vehicle energy supply
- Improves matching energy requirements to DRM-1 excursions
- Also an area of potential commonality among vehicles/planets

- Modularity of ECLSS supplies
- May extend excursion capabilities in some instances
- Reallocate supplies as necessary (nominal and contingency ops)

## Communication and Navigation

16.89 / ESD 352 Space Systems Engineering

## Comm / Nav Architecture Review

- Communication strategy
- What is needed where it is need as it is needed
- Navigation strategy
- Hybrid: gyroscope + odometer, map, beacon network
- Hard communication requirements:
- Must transport data from mobile to Earth at some point
- Must have continuous communications between the base and mobile regardless of line-of-sight
- Soft communication requirements:
- Should transport data from mobile to Earth continuously
- Should be extensible across all missions
- Should be cost-effective for required level of performance
- Amount of use system sees per dollar spent on the system

## Communications Evolvable Architecture

16.89 / ESD 352 Space Systems Engineering

## Ground Network Analysis

- Goal of analysis
- Determine if a ground network could replace a satellite
- Provides comparable performance at a fraction of the price

(items in red studied in detail)

## Ground Network Analysis Methodology

- Terrain models
- Use simulated terrain data to evaluate terrain effects on relays
- Based on power spectral density of lunar terrain

Smooth Mare

Hummocky Upland

Rough Mare

Rough Upland

- Analysis
- Start at point on map and move in straight direction
- Place relays when needed to maintain connectivity
- Determine how many relays required
- Metric: average distance between relays
- A measure of number of relays needed

## Trade between Range and Energy

- Limitation: uses line-ofsight (LoS) for connectivity
- LoS implies:
- All obstacles below LoS path
- Received energy approximately the same as transmitted energy less space loss due to distance
- Relaxing LoS assumption:
- Range will increase but received energy subject to knife-edge diffraction losses
- Can compensate for energy by using appropriate link margin

## Ground Network Analysis Methodology

- Design variables in the analysis

| Property | Parameterization |
| :---: | :---: |
| Terrain type | Four map data sets |
| Deployment strategy | Two relay placement algorithms |
| Start location | Set of starting site map locations |
| Relay height | Various heights (0 to 5 m$)$ |

- Parameter study
- Different maps
- Same map, different deployment strategies
- Same map, different start locations
- Same map, different relay heights

## Relay Deployment Strategies

- Straight-line deployment
- Drive in a straight line
- When connectivity lost, place relay behind
- Simplest deployment method
- Operationally easy, lower workload
- Upper bound on relay requirements
- Doesn't take advantage of local terrain (tops of hills)

End of visible area, place relay

- Adaptive deployment ("cannon method")
- Drive in a straight line
- When connectivity lost, place relay at nearby point of highest elevation that has connectivity
- Search within a specified radius (5-10 m away from vehicle)
- Straight-line better: problems with adaptive algorithm

## Straight-Line Deployment Simulation

16.89 / ESD 352 Space Systems Engineering

## Analysis Outputs

Relays on Elevation Map

Number of Connections Map

Connectivity Map

| Simulation Properties |  |
| :---: | :---: |
| Terrain type | Hummocky Upland |
| Deployment strategy | Straight-Line |
| Relay height | 1 m |

| Simulation Results |  |
| :---: | :---: |
| Number of relays | 12 |
| Average Connections | 3.43 |
| Distance / relay | 22.5 m |

## Parameter Study Results

## Parameter Study 1: Start Locations

 Hummocky Upland terrain, $1 m$ relays|  | Min |  | Max | Avg |
| :--- | :---: | :---: | :---: | :---: |
|  | Stdev |  |  |  |
| Number of relays | 8 | 13 | 9.9 | 1.5 |
| Avg connections | 2.3 | 4.3 | 3.1 | 0.6 |
| Distance / relay | 14.6 | 22.2 | 18.6 | 2.5 |

## Parameter Study 2: Terrain Types

 $1 m$ relays, straight-line deployment

Parameter Study 3: Relay heights Hummocky Upland terrain, straight-line

## Communication Conclusions

- Relay requirements are site specific
- Not just dependent on terrain type
- Rougher terrain requires more relays
- But even smooth terrain needs one every 20 m
- Inevitably large number of relays of reasonable size
- Significant improvements with higher relays (>0.5 m)
- Alternate deployment schemes \& terrain effects could help lower the number of required relays

## Communication Future Work

- Relax LoS assumption in analysis
- Incorporate knife-edge diffraction model
- Add trade off with power and antenna gain
- Consider improved deployment strategies
- Better adaptive deployment algorithms
- Introduce a priori global knowledge of terrain
- Integrate relay deployment with vehicle design and operations models

## Summary

16.89 / ESD 352 Space Systems Engineering

## Conclusions, Accomplishments

- Value delivering activities on the surface were captured in the four types of design reference missions
- Representative for major exploration surface activities
- Independently confirmed superiority of camper architecture
- Elimination of duplicate functionality and flexibility
- Created a set of subsystem models with more resolution compared to PSV
- Mostly physics-based / engineering-based models
- Created a versatile integrated capability modeling framework for surface operations based on vehicle designs
- Generated design specifications (including CAD) for an extensible planetary surface mobility system
- Dedicated UPV and camper designs, both with a common core and extensible modules for Earth, Moon, Mars environment customization
- Had fun, learned a lot

## Future Work

- Create more detailed subsystem models taking into account COTS, modularity, effects of geometrical design
- Further refine the interface between vehicle model and MUSE for more enhanced capability analysis
- Based on 16.89 results and future modeling:
- Build virtual and physical mockups (CAD, rapid prototyping, fullscale mockups)
- Use mock-ups for human factors, operability analysis
- Build a camper prototype and perform field testing
- MUSE
- Extend the analysis framework to Mars, Earth
- Incorporate terrain data for the entire planetary surface
- Extend to include ECLSS consumables
- Structure already in the code
- Incorporate more logistics, comm/nav

## Thank you

## Questions?

16.89 / ESD 352 Space Systems Engineering

## Backup Slides

16.89 / ESD 352 Space Systems Engineering

## Ground rules \& Assumptions (2)

- Pressurized mobility assets provide adequate shielding and life-support to survive and wait out a solar particle event (SPE)
- There exists a capability to forecast major flares with lag times between electromagnetic and particle radiation of less than an hour
- Capability is currently being developed (SOHO)
- Crew has to be able to return to a sheltered environment in under 3 hours in case of a SPE
- Limited exposure to SPE ionizing radiation flux is acceptable (see dosage limits for short-term exposure)

## Camper Dual Use: Re-Supply and Mobility

Human lunar lander concept using 2 crew compartments

$2^{\text {nd }}$ crew compartment could be common with camper

Camper used as
"lunar surface MPLM" before mobility use

- Camper crew compartment provides limited pressurized volume
- Same functionality as human lunar lander crew compartment
- Opportunity for commonality
- Opportunity for accretive build-up of a surface outpost
- Re-supply of an outpost on the lunar surface is key to long-duration lunar exploration (DRM-3)
- Non-trivial task, because of large amount of pressurized consumables
- Camper could serve as lunar surface MPLM before being used for surface mobility: option for dual use of mobility hardware resulting in cost-reduction

Possible Strategies to Improve Robustness

- Redundant coverage
- Drop 2 relays at each relay location
- Single fault-tolerant
- Sensitive to location-based disturbance

- Drop relays close enough to provide double coverage
- Single fault-tolerant
- Not as sensitive to location-based disturbance
- May require some power increase to compensate for terrain

## Possible Strategies to Improve Robustness

- Emergency power-ramping
- In event of a failed relay:
- Ramp up power to compensate for signal loss from terrain, distance
- Improve power efficiency by decreasing data rate
- Single fault-tolerant
- Time limitations before onboard power drops too far

## Possible Strategies to Improve Robustness

- Consider different antenna design concepts:

## Possible Strategy to Improve Robustness and Coverage

- Trade increased range for lower data rate in emergency
- Assumes navigation payload can achieve greater range
- Limitations for this strategy need to be analyzed

## Navigation Architecture

## - Trilateration

- Navigation payload on communication relay
- Navigation pings should have greater range than communications
- Use pinging process
 and clock synchronization to determine range

## Extensibility DRM 3 and DRM 4

- Approximate horizontal force ~ $6 \times 10^{\wedge} \mathbf{6} \mathrm{N}$
- Approximate digging/lifting force $\mathbf{\sim 2 , 2 9 6} \mathbf{N}$
- Average regolith density $\sim 1,250 \mathrm{~kg} / \mathrm{m}^{\wedge} 3$
- Moon gravity ~ 1.63 m/s^2
- Bucket Capacity ~ 0.04 m^3
- Based on SOLAR 010 and 015 Plus
- Lifting capacity $\sim 1,408 \mathrm{~kg}$
- Plowing ~6x10^6 N
- Towing ~ ?

| Average Bulk Density of Regolith $\mathrm{g} / \mathrm{cm}^{\wedge} 3$ <br> $\left(\mathrm{~kg} / \mathrm{m}^{\wedge} 3\right)$ |  | Depth range $(\mathrm{cm})$ |
| :--- | :--- | :--- |
| 1.50 | $(1500)$ | $0-15$ |
| 1.58 | $(1580)$ | $0-30$ |
| 1.74 | $(1740)$ | $30-60$ |
| 1.66 | $(1660)$ | $0-60$ |

## Science Payload

| UPV Payload |  |
| :--- | ---: |
| Time Of Flight-Mass Spectrometer | 10 kg |
| Mars Organic Analyzer | 11 kg |
| Spares and consumables | 4 kg |
| Survey equipment | 15 kg |
| Shovels, hammers, corers | 30 kg |
| Atmospheric samplers | 30 kg |
| Still/video cameras | 20 kg |
| Hand lenses | 2 kg |
| Aeolian sediment trap | 5 kg |
| Rock sample holders | 30 kg |
|  | 157 kg |

## Camper Payload

Drill (20 m) 250 kg
GC-MS (2) 75 kg
Optical microscope $\quad 15 \mathrm{~kg}$
APXS 5 kg
X-ray fluorescence $\quad 15 \mathrm{~kg}$
Amino acid, chirality analyzer 11 kg
Raman spectrometer 8 kg
Infrared spectrometer 8 kg
Solubility/wet lab 20 kg
Sample packaging/G/v. Box 150 kg
Computers 15 kg
Cameras 10 kg
Rock saw, grinder, sieves 10 kg
Metabolic analyzer 15 kg
Protein, DNA $\quad \begin{array}{r}25 \mathrm{~kg} \\ \hline 632 \mathrm{~kg}\end{array}$

## Human Activities Module

| Inputs | Outputs | In Modules | Out Modules |
| :--- | :--- | :--- | :--- |
| Number of Crew | Total Volume | Design Variables | Power |
| Excursion Duration | Lvng Space Height | Payload | Structure |
| Sci. Payload Vol | Length |  | Chassis |
| Sci. Payload Mass | Radius |  | Thermal |
| Num EVAs | Center to Floor |  |  |
|  | Floor Chord |  |  |
|  | Airlock Surf Area |  |  |
|  | Driving Power |  |  |
|  | Peak Power |  |  |
|  | Science Power |  |  |
|  | Night Power |  |  |
|  | Head Generated |  |  |
|  | Total Mass |  |  |
|  | Water Consump. |  |  |

## Human Activities Module

- Moon \& Mars Modifications
- Designed for these environments
- Only variations are input parameters, specifically number of crew and duration of excursion
- Earth Modifications
- Replace Airlock with kitchen

## Human Activities Module

- Basis
- number of crew on excursion
- duration of excursion in days
- volume required to conduct science
- mass of science tools required
- number of EVAs per excursion
- For Mars mobility, there seems to be a "gap" in performance between architectures using campers, and architectures using pressurized rovers
- Given constant speed and range, and given a certain DRM-1 configuration, there is an optimum number of days on traverse
- Sensitivity analysis will be performed on the influence of range and speed (both driving and walking)

## Original Modeling Approach (03/13)

Vehicle parameters

## Final Modeling Approach (Today)

IITIT

## Validation and Extensibility

- Where possible, model elements validated against Apollo LRV parameters and similar PSV models
- Some elements, such as wheel physics and motor characteristics, based directly on Apollo LRV data
- Current integrated design version implemented with aggregated/averaged parameters for speed, simplicity; could be extended via exhaustive lookup tables
- Mars extensibility: expect
- more benign terrain slopes and obstacles in most areas
- possibly worse soil interaction
- power increase due to gravity

## Results: Sample Collection on DRM-1

## At the end of a DRM-1 excursion...

$30 \%$ probability of running out of sample mass capacity

CDF of Sample Volume Capacity Remaining on UPV upon Return to Base for DRM1

Always have at least $77 \%$ sample volume capacity available
