Global Alignment of Protein Sequences
(NW, SW, PAM, BLOSUM)

## Topic 1 Info

- Overview slide has blue background - readings for upcoming lectures are listed at bottom of overview slide
- Review slides will have purple background
- Send your background/interests to TA for posting if reg'd for grad version
- PS1 is posted. BLAST tutorial may be helpful
- PS2 is posted. Look at the programming problem

## Local Alignment (BLAST) and Statistics

- Sequencing
- Conventional
- 2nd generation
- Local Alignment:
- a simple BLAST-like algorithm
- Statistics of matching
- Target frequencies and mismatch penalties for nucleotide alignments

## Questions: Chemistry / Library Prep

Dye terminator chemistry: dye is attached to base
How to put different adapters on the two ends?
At least three ways:

1) RNA ligation

2) polyA tailing/polyTVN-ad2priming/circularization (PMID 19213877)
3) ligation of Y-shaped adapters

## DNA Sequence Alignment I: Motivation

You are studying a recently discovered human non-coding RNA.
You search it against the mouse genome using BLASTN (N for nucleotide) and obtain the following alignment:

Q: 1 ttgacctagatgagatgtcgttcacttttactcaggtacagaaaa 45

S: 403 ttgatctagatgagatgccattcacttttactgagctacagaaaa 447

Is this alignment significant?
Is this likely to represent a homologous RNA?
How to find alignments?

## DNA Sequence Alignment II

Identify high scoring segments whose score S exceeds a cutoff $x$ using a local alignment algorithm (e.g., BLAST)

Scores follow an extreme value (aka Gumbel) distribution:

$$
P(S>x)=1-\exp \left[-K M N e^{-\lambda x}\right]
$$

For sequences/databases of length $\mathrm{M}, \mathrm{N}$ where $\mathrm{K}, \boldsymbol{\lambda}$ are positive parameters that depend on the score matrix and the composition of the sequences being compared

Conditions: expected score is negative, but positive scores possible

## Alternate algorithm

## Computational Efficiency

Measure efficiency in cpu run time and memory
O()$=$ "big-oh" notation (computational Order of problem)
Consider the number of individual computations required to run algorithm as a function of the number of 'units' in the problem (e.g., base pairs, amino acid residues)

Analyze the asymptotic worst-case running time or sometimes just do the experiment and measure run time If problem scales as square of the number of units it is

$$
\mathrm{O}\left(\mathrm{n}^{2}\right) \quad \text { "order } \mathrm{n} \text {-squared" }
$$

## DNA Sequence Alignment III

## How is $\lambda$ related to the score matrix?

$\lambda$ is the unique positive solution to the equation*:

$$
\sum p_{i, j} r_{j} e^{\lambda s_{i j}}=1
$$

$p_{i}=$ freq. of $n t i$ in query, $r_{j}=$ freq. of nt $j$ in subject
$\mathrm{S}_{\mathrm{ij}}=$ score for aligning an i,j pair
"Target frequencies"* : $q_{i j}=p_{i} r_{j} e^{\lambda s_{i j}}$

## DNA Sequence Alignment VI

Optimal mismatch penalty $m$ for given target identity fraction $r$

$$
m=\ln (4(1-r) / 3) / \ln (4 r)
$$

Examples:

| $r$ | 0.75 | 0.95 | 0.99 |
| :--- | :--- | :--- | :--- |
| $m$ | -1 | -2 | -3 |

$r=$ expected fraction of identities in high-scoring BLAST hits

## DNA Sequence Alignment VII

Meaning of mismatch penalty equation

$$
m=\ln (4(1-r) / 3) / \ln (4 r)
$$

Examples:

| r | 0.75 | 0.95 | 0.99 |
| :--- | :---: | :---: | :---: |
| m | -1 | -2 | -3 |

So why is $\mathrm{m}=-3$ better for finding matches with $99 \%$ identity?
Does it mean that you can only find $99 \%$ identical matches with a mismatch score of -3 ?
Answer: No. It's also possible to find $99 \%$ matches with $m=-1$ or -2 .
But $m$ changes the match length required to achieve statistical significance
$\lambda$ is the unique positive solution to the equation
$\sum_{i, j} p_{i} p_{j} e^{\lambda s s_{i j}}=1 \quad p_{i}=$ frequency of $n t i, s_{i j}=$ score for aligning an $i, j$ pair
and $P(S>x)=1-\exp \left[-K M N e^{-\lambda x}\right]$
If we change the mismatch score from -1 to $-3, \lambda$ will increase. Therefore, the score required to achieve a given level of significance will decrease, i.e. shorter hits will be significant.
So why would you ever want to use $m=-1$ ?

## Google: blastn

## DNA Sequence Alignment VIII

Translating searches:
translate in all possible reading frames
search peptides against protein database (BLASTP)
ttgacctagatgagatgtcgttcacttttactgagctacagaaaa
ttg|acc|tag|atg|aga|tgt|cgt|tca|ctt|tta|ctg|agc|tac|aga|aaa

| $\mathbf{L}$ | $\mathbf{T}$ | $\mathbf{x}$ | $\mathbf{M}$ | $\mathbf{R}$ | $\mathbf{C}$ | $\mathbf{R}$ | $\mathbf{S}$ | $\mathbf{L}$ | $\mathbf{L}$ | $\mathbf{L}$ | $\mathbf{S}$ | $\mathbf{Y}$ | $\mathbf{R}$ | $\mathbf{K}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

t|tga|cct|aga|tga|gat|gtc|gtt|cac|ttt|tac|tga|gct|aca|gaa|aa $\begin{array}{llllllllllllll}\mathbf{x} & \mathbf{P} & \mathrm{R} & \mathrm{x} & \mathrm{D} & \mathrm{V} & \mathrm{V} & \mathrm{H} & \mathrm{F} & \mathrm{Y} & \mathrm{x} & \mathrm{S} & \mathrm{T} & \mathrm{E}\end{array}$
tt|gac|cta|gat|gag|atg|tcg|ttc|act|ttt|act|gag|cta|cag|aaa|a $\begin{array}{lllllllllllllll}\mathrm{D} & \mathrm{L} & \mathrm{D} & \mathrm{E} & \mathrm{M} & \mathrm{S} & \mathrm{F} & \mathrm{T} & \mathrm{F} & \mathrm{T} & \mathrm{E} & \mathrm{L} & \mathrm{Q} & \mathrm{K}\end{array}$

Also consider reading frames on complementary DNA strand

## DNA Sequence Alignment IX

Common flavors of BLAST:

| Program | Query | Database |
| :---: | :---: | :---: |
| BLASTP | aa | aa |
| BLASTN | nt | nt |
| BLASTX | nt ( $\Rightarrow \mathrm{aa}$ ) | aa |
| TBLASTN | aa | nt ( $\Rightarrow$ aa) |
| TBLASTX | nt ( $\Rightarrow$ aa) | nt ( $\Rightarrow$ aa) |
| PsiBLAST | aa (aa msa) | a) aa |

msa = multiple sequence alignment

Which would be best for searching ESTs against a genome?

## Global Alignment of Protein Sequences (NW, SW, PAM, BLOSUM)

- Global sequence alignment (Needleman-Wunch-Sellers)
- Gapped local sequence alignment (Smith-Waterman)
- Substitution matrices for protein comparison

Background for today: Z\&B Chapters 4,5 (esp. pp. 119-125)

## Why align protein sequences?

- Functional predictions based on identifying homologous proteins or protein domains

## Assumes

Sequence similarity $\underset{\text { implies }}{ }$ Similarity in function (and/or structure)

- almost always true for similarity > 30\%
- $20-30 \%$ similarity is "the twilight zone"

BUT: Function carried out at level of folded protein, i.e. 3-D structure Sequence conservation occurs at level of 1-D sequence

## Converse is not true

Structural similarity

Sequence similarity (or even homology)

## Convergent Evolution

Unlikely to have ever had a common molecular ancestor
T. maritima ribosome recycling factor (RRF)

## Types of Alignments

## Scope:

- Local
- Global
- Semiglobal

## Scoring system:

- Ungapped
- Gapped
linear
affine

## Dot Matrix Alignment Example

Sequence \#1

What type of alignment would be most appropriate for this pair of sequences?

## Dot Matrix Alignment Example 2

Sequence \#1
Sequence \#2

## Gaps (aka "Indels")

- Linear Gap Penalty
$-\gamma(n)=n A, \quad n=n o$. of gaps, $A=$ gap penalty
- "Affine" gap penalty

$$
\begin{aligned}
& \mathbf{W}_{\mathrm{n}}=\mathbf{G}+\mathbf{n} \gamma, \\
& \mathbf{n}=\text { no. of gaps, } \gamma=\text { gap extension penalty, } \\
& \quad \text { and } \mathbf{G}=\text { gap opening penalty } \\
& \mathbf{W}_{\mathrm{n}}=\mathbf{G}+(\mathrm{n}-1) \gamma
\end{aligned}
$$

Or:
with alternative definition of gap opening penalty

## Obtain optimal global alignment using Dynamic Programming:

First write one sequence across the top, and one down along the side

|  | Gap | V | D | S | C |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Gap | 0 | 1 gap | 2 gaps |  |  |
| V | 1 gap |  |  |  |  |
| E | 2 gaps |  |  |  |  |
| S |  |  |  |  |  |
| L |  |  |  |  |  |
| C |  |  |  |  |  |

Note - linear gap penalty: $\gamma(n)=n A$, where $A=$ gap penalty a negative number

## Dynamic Programming:

Initialize the alignment matrix

|  |  | $i=0$ | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| j |  | Gap | V | D | S | C | Y |
| 0 | Gap | 0 | -8 | -16 | -24 | -32 | -40 |
| 1 | V |  | S |  |  |  |  |
| 2 | E | -16 |  |  |  |  |  |
|  |  |  | $\mathbf{S i j}=$ score of optimal alignment ending at position $\mathbf{i}$ in |  |  |  |  |
| 3 | S | -24 |  | $\begin{aligned} & \text { and } \mathbf{j} \\ & \text { I), } \mathbf{S}(\mathrm{i} \end{aligned}$ | $\begin{aligned} & \text { eq } 2 . \\ & \text { j)... } \end{aligned}$ | uires | we |
| 4 | L | -32 | Rec solu | sive: ns to | ution aller | ger | em |
| 5 | C | -40 | Stor | Sij and | ow w | ved | in |
|  |  |  | Ofte | called | nam | gram | g' or |
| 6 | Y | -48 | 'rec | ive o | izati |  |  |

What is the gap penalty in this example?

## Dynamic Programming: Recursion

## Sequence 1

2 E -16

Global alignments: Needleman-Wunsch-Sellers
3 S -24
4 L -32

5 C -40

| 5 | C | -40 | 30 | -22 |  |  |  |
| 6 | Y | -48 | 38 | -30 | -15 |  |  |

## Semiglobal Alignment

Allow sequences to overhang at either end without penalty -usually gives better alignments of homologous sequences of different lengths

Same algorithm as before except

- initialize edges of DP matrix $\mathrm{S}_{\mathrm{i}, 0}$ and $\mathrm{S}_{\mathbf{0 , j}}$ to 0
- instead of requiring traceback to begin at $\mathrm{S}_{\mathrm{m}, \mathrm{n}}$, allow it to begin at highest score in bottom row or rightmost column

## Gapped Local Alignment

Temple Smith and Michael Waterman, 1981 - modified Needleman-Wunsch-Sellers

Local alignment is the best scoring alignment of a substring in sequence $x$ to a substring in sequence $y$.

Key idea is not to force the alignment to extend to the ends of the sequences

## Smith-Waterman Local Alignment

## Again, use dynamic programming

Same basic scheme as before except

- similarity matrix MUST include negative values for mismatches and
- when the value calculated for a position in the scoring matrix is negative, the value is set to zero - this terminates the alignment

## Smith-Waterman:

Write one sequence across the top, and one down along the side

Need a metric of similarity between amino acid pairs
Simplest metric - identity matrix

|  | A | C | D | E | F | G | H | I | K |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| A | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| C |  | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| D |  |  | 1 | 0 | 0 | 0 | 0 | 0 | 0 |
| E |  |  |  | 1 | 0 | 0 | 0 | 0 | 0 |
| F |  |  |  |  | 1 | 0 | 0 | 0 | 0 |
| G |  |  |  |  |  | 1 | 0 | 0 | 0 |
| H |  |  |  |  |  |  | 1 | 0 | 0 |
| 1 |  |  |  |  |  |  |  | 1 | 0 |
| K |  |  |  |  |  |  |  |  | 1 |

OK for nucleic acids, but for proteins can do substantially better

What properties should an amino acid similarity matrix have?

## Refer to Z\&B pp. 119-125

# Scoring system should favor matching identical or related amino acids and penalize for poor matches and for gaps 

Need to know how often a particular amino acid pair is found in related proteins compared with its occurence by chance, and also how often gaps (insertions/deletions) are found in related proteins relative to dissimilar amino acid pairs

## Scores and Evolution

Any alignment scoring system brings with it an implicit evolutionary model

## Amino Acid Substitution Matrices

## Margaret Dayhoff, 1978, PAM Matrices

## Explicit evolutionary model

Assumes symmetry: $A \rightarrow B=B \rightarrow A$
Assumes amino acid substitutions observed over short periods of time can be extrapolated to long periods of time

71 groups of protein sequences, $85 \%$ similar 1572 amino acid changes.

Functional proteins $\rightarrow$ mutations "accepted" by natural selection

PAM1 matrix means $1 \%$ divergence between proteins - i.e. 1 amino acid change per 100 residues. Some texts re-state this as the probability of each amino acid changing into another is $\sim 1 \%$ and probability of not changing is $\sim 99 \%$

## Construction of a Dayhoff Matrix: PAM1

Step 1: Measure pairwise substitution frequencies for each amino acid within families of related proteins that can be confidently aligned

900 Phe (F) remained F
100 Phe (F) $\rightarrow 80$ Tyr (Y), 3 Trp (W), 2 His (H)....
Gives $n_{a b}$, i.e. $\quad n_{Y F}=80$

$$
n_{\mathrm{WF}}=3
$$

....in evolution

## DNA Sequence Evolution

## Markov Model (aka Markov Chain)

## Classical Definition

## Stochastic Process:

- a random process or
- a sequence of Random Variables

A discrete stochastic process $\mathrm{X}_{1}, \mathrm{X}_{2}, \mathrm{X}_{3}, \ldots$
which has the Markov property:

$$
P\left(X_{n+1}=j \mid X_{1}=x_{1}, X_{2}=x_{2}, \ldots X_{n}=x_{n}\right)=P\left(X_{n+1}=j \mid X_{n}=x_{n}\right)
$$

(for all $\mathrm{x}_{\mathrm{i}}$, all j, all n )

In words:
A random process which has the property that the future (next state) is conditionally independent of the past given the present (current state)

Andrey Markov, a Russian mathematician (1856-1922)
