## Lecture 10- summary

No material or structural element can sustain infinite load!

**Physical reason:** Atomic bonds inside a material can only sustain a critical load, on the order of a few nN.

Therefore - need to satisfy two condition in structural problems:

- 1. Static equilibrium, that is, statically admissible (S.A.)
- 2. Strength compatibility (S.C.)

$$\forall i; \ \overrightarrow{F}^{ext}\left(\overrightarrow{x}_{i}\right) + \overrightarrow{R}\left(\overrightarrow{x}_{i}\right) + \sum_{j} \overrightarrow{F}_{S}^{j}\left(\overrightarrow{x}_{i}\right) \stackrel{\text{s.A.}}{=} 0$$

$$\forall j; \ \overrightarrow{F}_{S}^{j} \in D_{S} \Leftrightarrow f\left(F_{S}^{j} = \overrightarrow{F}_{S}^{j} \cdot \overrightarrow{n}_{j}\right) \stackrel{\text{s.C.}}{\leq} 0$$

Expression of S.C. in terms of material strength  $\sigma_0$ :

$$\forall j; \ f = \left| F_S^j \right| - (\sigma_0 A)^j \le 0$$

8 7 3 Robustness ratio 6 gamma\_1/gamma<sub>.</sub> for 5  $A_2$ 4 3 2  $A_3$ 1 0 50 100 0  $A_1/A_3=2$  same strength  $\sigma_0$ Angle phi

Same robustness for 30 degree angle

Failure occurs simultaneously in all rods
