Real-Time Control Strategies for Rail Transit

Outline:

- Problem Description and Motivation
- Model Formulation
- Model Application and Results
- Implementation Issues
- Conclusions

Problem Context

- High frequency urban rail service (e.g. headways of 2-10 minutes)
  - passengers arrive randomly
  - service regularity is a key goal
  - $E(WT) = \frac{E(H)}{2}[1 + cov(H)^2]$
- Branching route structure
- Central real-time train location information and dispatch capability

Three Levels of Control Problems

Routine disturbances - several minutes' deviation from schedule

Control Strategies:

- **speed adjustment**
- **dwell time adjustment (selective holding) terminal recovery**

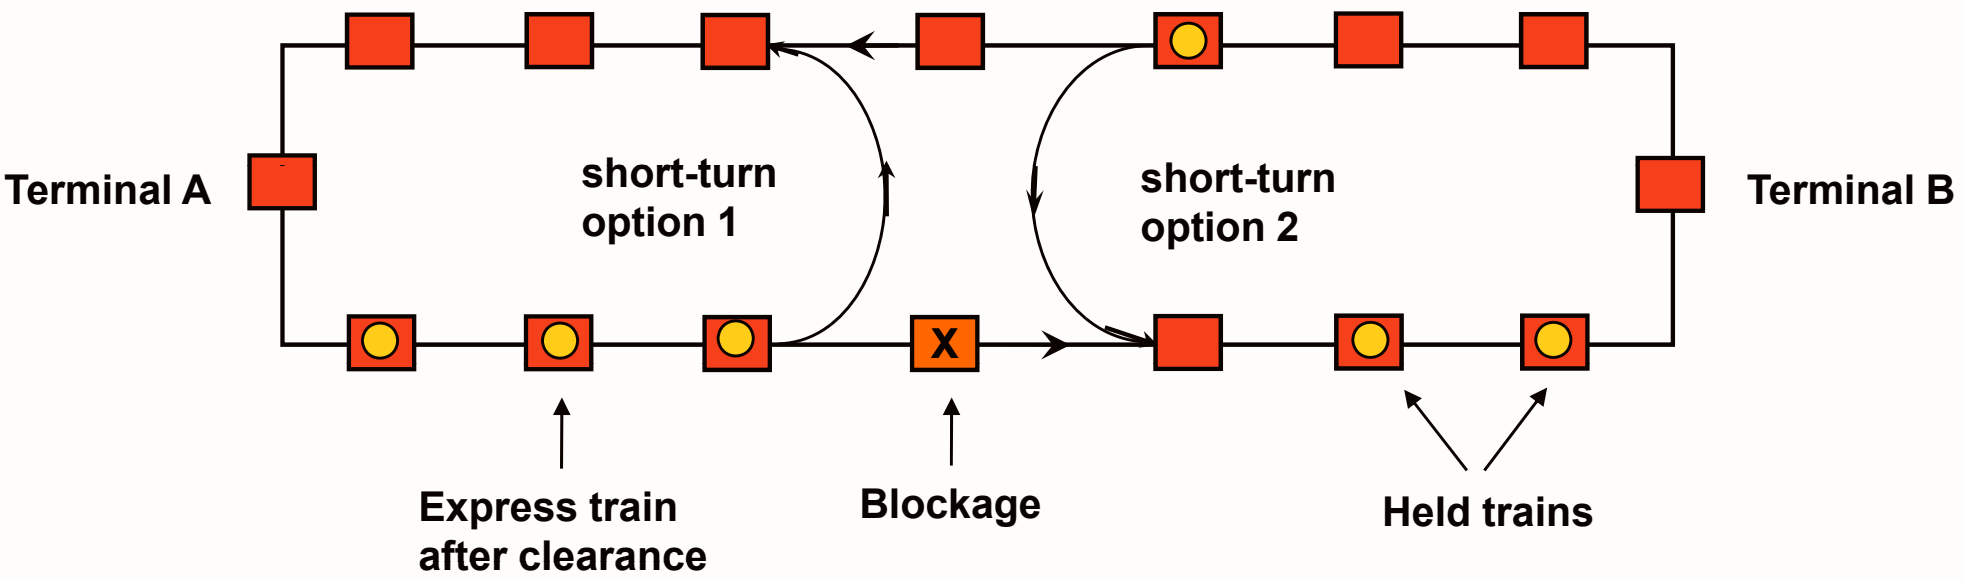
Short-term disruptions: 5-30 minute blockages on the line

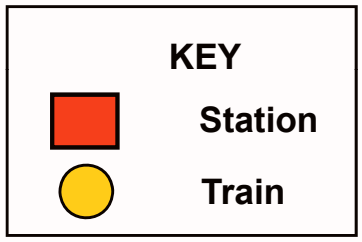
Longer-term disruptions - greater than 30 minute blockages

Control Strategies:

- **single-track reverse direction operations**
- **replacement bus service around blockage**

Disruption Response Strategies

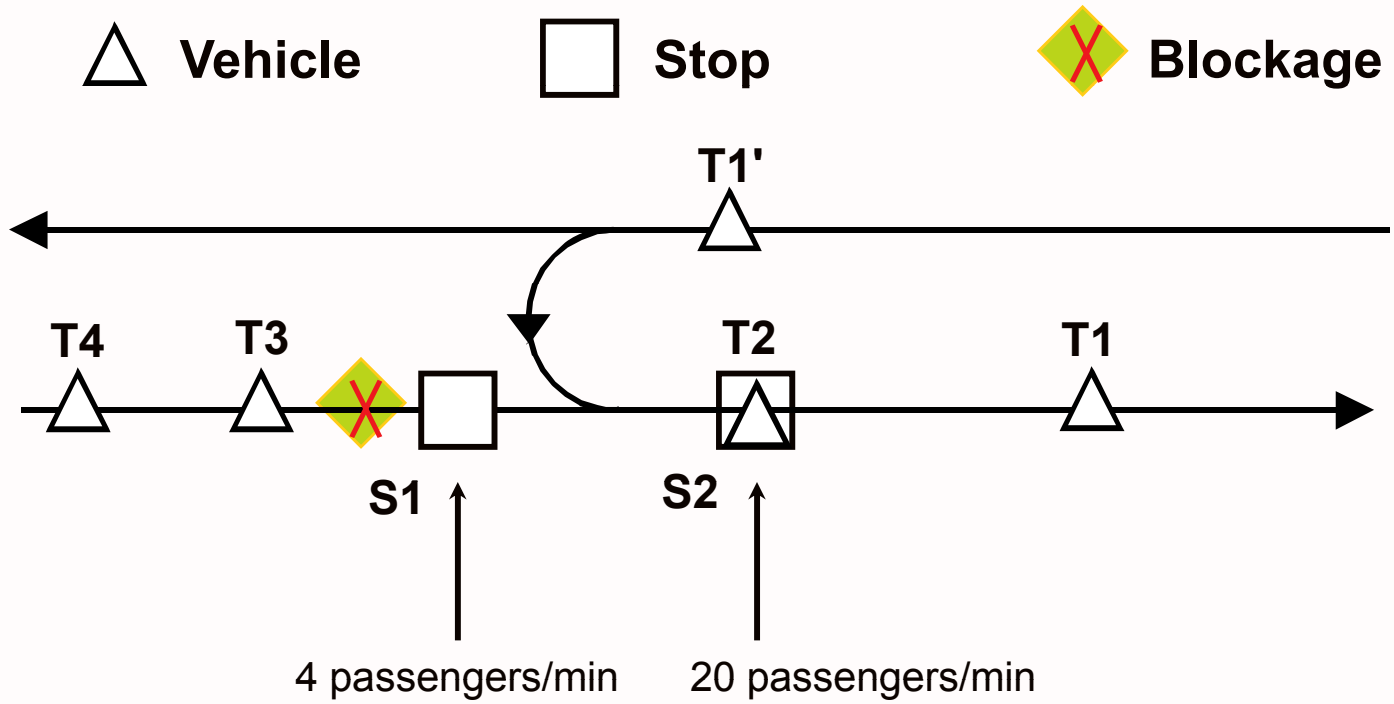




Problem Description

- Overall Objective:
  - Develop a real-time decision support system to determine control strategies to recover from disruptions
- Specific Objective:
  - Minimize passenger waiting times (implies maintaining even headways)
- Key Characteristics:
  - Instability of even headways
  - Passenger sensitivity to long waiting time and crowding
  - Cost insensitivity to different strategies
- Possible Strategies:
  - Holding
  - Short-turning
  - Expressing

Example of Transit Control Strategies



- 6-minute scheduled headways
- 3-minute minimum safe headway
- 10-minute disruption
- impact set includes trains T2, T3, and T4 and stations S1 and S2

Example Results

1. Do nothing: h_{T_2} = 6 mins.; h_{T_3} = 16 mins.; h_{T_4} = 3 mins.

$$\textit{Total Passenger Waiting Time} = \frac{1}{2}\left[4(16^2+3^2)\right] + \frac{1}{2}\left[20(6^2+16^2+3^2)\right] = 3540 \text{ pass} - \text{mins.}$$

2. Holding: Hold T2 at S2 for 4 mins.
Then at S2: h_{T_2} = 10 mins.; h_{T_3} = 12 mins.; h_{T_4} = 3 mins.

$$TPWT = \frac{1}{2}\left[\left(4(16^2+3^2)+20(10^2+12^2+3^2)\right)\right] = 3060 \text{ pass} - \text{mins.}$$

3. Expressing: Express T3 past S1 to save 1 minute in travel time.
Then at S2: h_{T_2} = 6 mins.; h_{T_3} = 15 mins.; h_{T_4} = 4 mins.

$$TPWT = \frac{1}{2}\left[4*19^2+20(6^2+15^2+4^2)\right] = 3492 \text{ pass} - \text{mins.}$$

Model Formulation

Key Features:

- station specific parameters: passenger arrival rates, alighting fractions, minimum safe headways
- station dwell time a linear function of passengers boarding, alighting and crowding
- train order is variable
- train capacity constraint

Simplifications:

- predictable disruption length
- passenger flows estimated from historical data
- system is modelled as deterministic
- strategies selected to produce minimum inter-station travel times.

Model Formulation

Decision Variables: departure time of train *i* from station *k*

Objective function: minimization of passenger waiting time

- ***quadratic function approximated by a piecewise linear function***

Impact Set: consider a finite set of trains and stations and approximate the effects beyond this set

Constraints: train running time and minimum safe headways

- ***other relationships govern passenger loads, train dwell times***

Model Structure: mixed integer program except if passenger capacity is not binding when it is a linear program

Specific Models

Holding Strategy Models:

- Hold all
- Hold once
- Hold at first station

Combined Short-turning and Holding Models:

- Predetermined train order
- Undetermined train order

Model Application

MBTA Red Line Characteristics:

- 23 stations (including 3 terminals)
- 27 six-car trains in A.M. peak
- 3.4 minute trunk headways (6 and 8 minutes on branches)
- 30,000 passengers in peak hour

		TPT	51201	10488	55396

Execution Times

- Sun SPARC 20 workstation
- GAMS V. 2.25
- CPLEX V. 3.0
- Simple front-end heuristic to fix some binary variables

Large Problems:	**11-13 trains, 69-95 train/station decision var.**
Execution Time:	**10 out of 16 <30 sec.**
Realistic Size:	**7-8 trains, 40-50 train/station decision var.**
Execution Time:	**16 out of 16 <34 sec.**

Conclusions

- Holding and short-turning models formulated and solved to optimality
- Active control strategies result in significant passenger waiting time savings
- Train control set can be reduced to trains ahead of the blockage
- Train control set need not be large

Conclusions

- Hold at First or Hold Once strategies *can* be almost as effective as Hold All strategy
- Short-turning most effective where:
  - -- blockage is long relative to short-turn time
  - -- number of stations outside the short-turn loop is small
- Consideration of on-board time is desirable
- Execution time is 30_{secon} ds or less but faster heuristics are probably achievable
