## Elasticity

## Elastic and inelastic behavior

For small strains at constant temperatures, the amount of strain is determined by the magnitude of the stress causing it.
Perfectly Elastic:
Purely elastic behavior implies thermodynamic reversibility. All the work put into deforming the body is recoverable. Deformation is not timedependent.
The relation between stress and strain may be linear or non-linear.
Anelastic:
Time-dependent behavior in which the material strain is recoverable
Plastic and viscoplastic behavior:
When a material is deformed to large strains, some of the strain is permanent and not recoverable; this permanent strain is plastic (if time independent) or viscoplastic (if time dependent).

| Elastic |  | Recoverable | Time- <br> independent | Linear |
| :--- | :--- | :--- | :--- | :--- |
|  |  |  |  | Nonlinear |
| Inelastic | Anelastic | Part. Recov. | Time- <br> dependent | Lin or Non- <br> lin. |
|  | Plastic | Not recover. | Time-indep. | " |
|  | Visco-plas. |  | time-dep | " |

## Coordinate Conventions for Elasticity Tensor

The exact values of the elasticity tensor depend on the definition of the coordinate system.
The convention used is that the modulii are referred to an othonormal coordinate systems, $\mathrm{x}_{1}, \mathrm{x}_{2}, \mathrm{x}_{3}$, with unit vectors, $\hat{\mathbf{e}}_{1}, \ldots$. These axes are related to the mineral lattice vectors by the following convention

| Monoclinic | $\hat{\mathbf{e}}_{2} \\| \underset{\sim}{\mathbf{b}}$ |
| :--- | :--- |
| Tetragonal, <br> trigonal, <br> hexagonal | $\hat{\mathbf{e}}_{1}\left\\|\underset{\sim}{\mathbf{a}}, \hat{\mathbf{e}}_{3}\right\\| \mathbf{\sim}$, |
| Orthorhombic <br> and cubic | $\hat{\mathbf{e}}_{1}\left\\|\underset{\sim}{\mathbf{a}}, \hat{\mathbf{e}}_{2}\right\\| \underset{\sim}{\mathbf{b}}, \hat{\mathbf{e}}_{3} \\| \mathbf{c}$, |

## Linear Elastic Equations

Given the restrictions of reversibility and linearity,
Hooke's law can be written for strain as a function of stress

$$
\begin{array}{ll}
\varepsilon_{i j}=c_{i j k l} \sigma_{k l}(i, j, k, l=1, \ldots, 3) & \varepsilon_{I}=c_{I J} \sigma_{J}(I, J=1, \ldots, 6) \\
\sigma_{i j}=s_{i j k l} \varepsilon_{k l}(i, j, k, l=1, \ldots, 3) & \varepsilon_{I}=c_{I J} \sigma_{J}(I, J=1, \ldots, 6)
\end{array}
$$

The matrix notation (right-hand set of equations) reduces the number of subscripts to two, but the equations do not strictly obey tensor transformation rules and require factors of 2 and 4 to be inserted in the relations between $s_{i j k l}$ and $s_{I J}$.

| $\mathbf{s}$ | Compliance | Modulus | Stress $^{-1}$ |
| :--- | :---: | :---: | :---: |
| $\mathbf{c}$ | Stiffness | Constant | Stress |

The reduction from 81 separate components to 36 occurs because the stress and strain tensors are symmetric.

Because the material behavior is thermodynamically reversible, a chemical potential energy, the Helmholtz free energy, can be defined to express the energy of the elastic solid. For this thermodynamic potential to exist, requires the stiffness and compliance tensors and matrices to be symmetric. This limits the number of independent components of the most general elasticity tensor to 21 .

## Symmetry causes further restrictions:

Crystal symmetry requires further reductions in the number of the stiffnesses and compliances

## Elastic stiffness or compliance in an arbritrary direction

## Vector Transformation

Express the components of a vector in a new coordinate system that has been rotated. The components of the vector in the new system are

$$
E_{i}^{\prime}=a_{i j} E_{j}
$$

where $E_{i}$ are the components of the vector in the old system, $a_{i j}$ are the direction cosines between the old and new coordinate systems, and $E_{j}$ ' are the components in the new system.

Tensor Transformation:
Tensors of the second rank transform in much the same way as vectors:

$$
E_{i j}^{\prime}=a_{i k} a_{j l} E_{k l}
$$

Tensors of the fourth rank (like stiffness or compliance) transform as

$$
s_{i j k l}^{\prime}=a_{i m} a_{j n} a_{k o} a_{l p} s_{m n o p}
$$

Thus, the Young's modulus ( $c_{1111}$ ) could be calculated in any arbitrary direction.

## Relations among moduli, stiffnesses and compliances

In isotropic elastic materials, the most commonly used elastic (moduli, constants, stiffnesses, compliances) are Young's Modulus, the Bulk modulus, the Volumetric compressibility, Poisson's ratio, and the Lame parameters.

## Young's Modulus

The relation between the load on a bar and the fractional stretch of a bar along its long axis is known as Young's modulus.

$$
\sigma_{l}=E \varepsilon_{l} \quad \varepsilon_{l}=\frac{1}{E} \sigma_{l}
$$

where the subscript $l$ is used to indicate the direction in which the measurement is made, but in an isotropic material the direction is immaterial.

In an anisotropic material, the equivalent measurement depends on the direction (relative to some fixed axes in the material) in which the measurement is made).

When the measurement is made along the 1 axis in a single crystal, the equivalent modulus (stiffness, compliance) is

$$
\sigma_{11}=c_{1111} \varepsilon_{11} \text { equivalently } \sigma_{1}=c_{11} \varepsilon_{1} \quad \text { or } \quad \varepsilon_{11}=s_{1111} \sigma_{11}
$$

When the Young's modulus measurement is made in the 1 direction,

$$
E=1 / s_{1111}
$$

When the measurement is made in another direction D
$1 / E=a_{D i} a_{D j} a_{D k} a_{D l} s_{i j k l}$
where $a_{D i}$ is the direction cosine between D and the axis i .

## Some typical values of compressibility and Poisson's ratio

| Rock/Material | Compressibility $\left(10^{-5} \mathrm{MPa}^{-1}\right)$ | Poisson's Ratio |
| :--- | :---: | :---: |
| Obsidian | $2.9-3$. | $0.12-0.16$ |
| Granite | $1.9-2.0$ | $0.23-0.27$ |
| Diorite | $1.4-1.7$ | $0.26-0.29$ |
| Gabbro | $1.1-1.3$ | $0.27-0.31$ |
| Diabase | $1.2-1.4$ | $0.27-0.30$ |
| Dunite | $0.8-0.9$ | $0.26-0.28$ |
| Slate | $1.9-2.3$ | $0.15-0.20$ |
| Limestone | $1.3-1.4$ | $0.27-0.30$ |
| Dolomite | $1.0-1.1$ | 0.30 |
| Quartzite | $2.4-2.6$ | $0.12-0.15$ |
| Mica Schist | $2.1-2.3$ | $0.15-0.20$ |
| Feldspathic Gneiss | $1.8-2.2$ | $0.15-0.20$ |
| Amphibolite | $1.1-1.3$ | $0.28-0.30$ |
| Oligoclase | $1.5-1.6$ | 0.29 |
| Anorthosite | $1.2-1.4$ | 0.31 |
| Rocksalt | 4.3 | 0.25 |
| Anhydrite | 1.8 | 0.30 |
| Ice | 12 | 0.36 |
| Steel | 0.6 | $0.28-0.29$ |
| Aluminum | 1.3 | $0.34-0.36$ |

## Poisson's Ratio

$\nu \equiv \frac{-\varepsilon_{\perp l}}{\varepsilon_{l}}$
for an isotropic material $\sigma_{l}=E \varepsilon_{l}$

$$
s_{22111}=\frac{\varepsilon_{22}}{\sigma_{11}}=\frac{\varepsilon_{22}}{E \varepsilon_{11}}=\frac{v}{E}=s_{21}
$$

For rocks, Poisson's ratio is commonly 0.25 . In some materials, it may be very small or even negative.

Can you think of a common use for a material with a low or negative Poisson's ratio?
For an incompressible material, Poisson's ratio is 0.5 .
Why?
Is it possible for $v$ to be even larger than that?
Rigidity Modulus

$\mu \varepsilon_{\text {shear }}=\sigma_{\text {shear }}$
When the body and the crystal axes are aligned, $S_{44}=\frac{1}{\mu}$

## Lamé Constants

For an isotropic material, the stress strain relations are often written:

$$
\begin{aligned}
& \sigma_{1}=(\lambda+2 \mu) \varepsilon_{1}+\lambda \varepsilon_{2}+\lambda \varepsilon_{3} \\
& \sigma_{2}=\lambda \varepsilon_{1}+(\lambda+2 \mu) \varepsilon_{2}+\lambda \varepsilon_{3} \\
& \sigma_{3}=\lambda \varepsilon_{1}+\lambda \varepsilon_{2}+(\lambda+2 \mu) \varepsilon_{3}
\end{aligned}
$$

From the equations above it is clear that if the crystal axis 1 is aligned with the exterior axis 1 then

$$
2 \mu+\lambda=c_{1111} \text { and } c_{1122}=\lambda
$$

## Compressibility

Consider imposition of pressure $\sigma_{i j}=-p \delta_{i j}$
Then the equation for the strain is
$\varepsilon_{i j}=-p s_{i j k l} \delta_{k l}$
define $\Delta \equiv \varepsilon_{i i}=-p s_{i i k k}$
and $\beta_{T}=-\frac{\Delta}{p}=s_{i i k k}$

Write the equation for the isothermal compressibility for a cubic crystal.

$$
\beta_{\text {Tcubic }}=3\left(s_{11}+2 s_{12}\right)
$$

Does the compressibility depend on the direction of measurement?
The bulk modulus is the inverse of the compressibility.

## Relations among Various Moduli and Elastic

## Constants

| Name | Symbol | Definition | S/C | Units | Relations |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Inv. Young's Modulus | 1/E | Normal Strain Normal Stress | $\mathrm{S}_{1111}$ | Stress ${ }^{-1}$ | $\frac{\lambda+\mu}{\mu(3 \lambda+2 \mu)}$ |
| Poisson's Ratio | $\nu, \sigma$ | $\frac{\text { Normal Strain }}{\perp \text { Norm. Strain }}$ | $\begin{aligned} & \mathrm{S}_{2211} \\ & / \mathrm{S}_{1111} \end{aligned}$ | --- | $\frac{\lambda}{2(\lambda+\mu)}$ |
| Shear Modulus | $\mu, \mathrm{G}$ | Shear Stress <br> Shear Strain | $\mathrm{C}_{1212}$ | Stress | $\frac{E}{2(1+v)}$ |
| Lame Const. | $\lambda$ | Response of Stress to Volum.Change | $\mathrm{C}_{1111}$ | Stress | $\lambda=\frac{E v}{(1+v)(1-v)}$ |
| Compressibility | B | Dilation/Pressure |  | Stress ${ }^{-1}$ | $\frac{E}{3(1-2 v)}=\lambda+2 \frac{\mu}{3}$ |

## Equivalent formulations for isotropic elastic materials in

 principal stress representation:$$
\begin{array}{ll}
\varepsilon_{11}=\frac{1}{E} \sigma_{11}-\frac{v}{E} \sigma_{22}-\frac{v}{E} \sigma_{33} & \sigma_{1}=(\lambda+2 \mu) \varepsilon_{1}+\lambda \varepsilon_{2}+\lambda \varepsilon_{3} \\
\varepsilon_{22}=\frac{1}{E} \sigma_{11}-\frac{v}{E} \sigma_{22}-\frac{v}{E} \sigma_{33} & \sigma_{2}=\lambda \varepsilon_{1}+(\lambda+2 \mu) \varepsilon_{2}+\lambda \varepsilon_{3} \\
\varepsilon_{33}=-\frac{v}{E} \sigma_{11}-\frac{v}{E} \sigma_{22}+\frac{1}{E} \sigma_{33} & \sigma_{3}=\lambda \varepsilon_{1}+\lambda \varepsilon_{2}+(\lambda+2 \mu) \varepsilon_{3}
\end{array}
$$

In general:

$$
\varepsilon_{i j}=\frac{1+v}{E} \sigma_{i j}-\frac{v}{E} \delta_{i j} \sigma_{k k}
$$

$$
\sigma_{i j}=\lambda \delta_{i j} \varepsilon_{k k}+2 \mu \varepsilon_{i j}
$$
