## Problem 7.14

This problem is from "Advanced Fluid Mechanics Problems" by A.H. Shapiro and A.A. Sonin

A fluid of density $\rho$ and viscosity $\mu$ flows through a long pipe of diameter $D$ at the volume flow rate $Q$.
(a) Demonstrate that if the flow is laminar (i.e., totally steady) and fully developed (the velocity profile and the pressure gradient no longer change with downstream distance $x$ ), the pressure gradient in the direction of flow must have the form

$$
\frac{d p}{d x}=-K \frac{Q \mu}{D^{4}}
$$

where $K$ is constant.
(b) Demonstrate that if the flow is turbulent (i.e., unsteady) but steady and fully developed in the mean, the mean pressure gradient in the direction of flow must have the form

$$
\frac{d p}{d x}=\left(\frac{\rho Q^{2}}{D^{5}}\right) \cdot \phi\left(\frac{\rho Q}{\mu D}\right)
$$

## Solution:

Consider flow through a pipe:

| $\frac{d p}{d x}$ | $Q$ | $D$ | $\rho$ | $\mu$ |
| :---: | :---: | :---: | :---: | :---: |
| $\left[\mathrm{ML}^{-2} \mathrm{~T}^{-2}\right]$ | $\left[\mathrm{L}^{3} \mathrm{~T}^{-1}\right]$ | $[\mathrm{L}]$ | $\left[\mathrm{ML}^{-3}\right]$ | $\left[\mathrm{ML}^{-1} \mathrm{~T}^{-1}\right]$ |

(a) Laminar Case

Steady and fully-developed $\Rightarrow$ INERTIA-FREE and $d p / d x \neq f(\rho)$

$$
\begin{aligned}
& \therefore \frac{d p}{d x}=f_{1}(\mu, Q, D) \\
& n=4 \text { variables } \\
& k=3 \text { primary variables } \\
& \Rightarrow j=1 \text { dimensionless group }
\end{aligned}
$$

Our primary variables must be $\mu, Q$, and $D$ (since there are no other variables)

$$
\begin{gathered}
\Pi=\frac{d p}{d x} \mu^{a} Q^{b} D^{c} \\
{[]=\left[\mathrm{M}^{0} \mathrm{~L}^{0} \mathrm{~T}^{0}\right]=\left[\mathrm{ML}^{-2} \mathrm{~T}^{-2}\right]\left[\mathrm{ML}^{-1} \mathrm{~T}^{-1}\right]^{a}\left[\mathrm{~L}^{3} \mathrm{~T}^{-1}\right]^{b}[\mathrm{~L}]^{c}} \\
\mathrm{M}^{0}=\mathrm{M}^{1} \mathrm{M}^{\mathrm{a}} \quad \Rightarrow a=-1 \\
\mathrm{~T}^{0}=\mathrm{T}^{-2} \mathrm{~T}^{1} \mathrm{~T}^{-\mathrm{b}} \quad \Rightarrow b=-1 \\
\mathrm{~L}^{0}=\mathrm{L}^{-2} \mathrm{~L}^{1} \mathrm{~L}^{-3} \mathrm{~L}^{\mathrm{c}} \quad \Rightarrow c=4 \\
\Rightarrow \Pi=\frac{d p}{d x} \cdot \frac{D^{4}}{\mu Q}=\mathrm{constant}
\end{gathered}
$$

Keep in mind that $\frac{d p}{d x}$ and $Q$ have opposite signs (i.e., $\frac{d p}{d x}>0$ when $Q<0$ and vice versa). Therefore, define constant $-K$ to ensure that $K \geq 0$.

$$
\Rightarrow \frac{d p}{d x}=-K \frac{\mu Q}{D^{4}}
$$

(b) Turbulent Case

Steady, and fully-developed in the mean

$$
\begin{aligned}
\therefore & \frac{d p}{d x}=f_{2}(\mu, \rho, Q, D) \\
n & =5 \text { variables } \\
k & =3 \text { primary variables } \\
\Rightarrow j & =2 \text { dimensionless groups }
\end{aligned}
$$

For our primary variables, we choose (1) a fluid property: $\rho,(2)$ a flow parameter: $Q$, and (3) a geometric parameter: $D$. Follow the same procedure as in part (a) to find

$$
\begin{aligned}
\Pi_{1} & =\frac{d p}{d x} \cdot \frac{D^{5}}{\rho Q^{2}} \\
\Pi_{2} & =\frac{\mu D}{\rho Q}
\end{aligned}
$$

Since $\Pi_{1}=\phi\left(\Pi_{2}\right)$,

$$
\frac{d p}{d x}=\frac{\rho Q^{2}}{D^{5}} \phi\left(\frac{\mu D}{\rho Q}\right)
$$
